I. INTRODUCTION

Magnetic materials are the necessary components of the magnetic memory and microwave devices. Ferromagnetic resonance and permeability measurements provide a basis for the design and characterization of magnetic materials and the development of new devices. Here, we demonstrated a wideband (10 MHz-26 GHz) rf magnetic metrology system that combines FMR spectrometer and permeameter. The system enables the characterization of the complex permeability, FMR linewidth, saturation magnetization, effective anisotropy field, Gilbert damping, inhomogeneous linewidth broadening, and gyromagnetic ratio. The demonstration has been performed on in-plane samples of 30 nm FeGaB and 2 nm NiFe films, and ultra-thin FeCoB/MgO multilayers with perpendicular magnetic anisotropy (PMA). In addition, the permeability measurements do not need expensive vector network analyzer (VNA) and show 40-50 dB higher SNR over the other permeameters.

II. EXPERIMENT AND RESULTS

The proposed rf magnetic metrology system is established from the FMR spectrometer presented in the previous report [7], which uses a microwave source instead of a VNA. The signal detected is proportional to the field derivative of the microwave power. The FMR data are plotted in Fig.1 for the in-plane 30 nm FeGaB and 2 nm NiFe films, and a FeCoB/MgO multilayer with PMA. For the in-plane films, the saturation magnetization \(M_s\), anisotropy field \(H_k\) can be extracted from the FMR results. The gyromagnetic ratio \(\gamma\) and effective perpendicular field \(H_{eff}\) and damping constant \(\alpha\) can be extracted for the PMA sample.

The complex permeability is defined as \(\mu = \mu' + i \mu''\), where \(\mu'\) and \(\mu''\) are the real and imaginary part of permeability respectively. The initial permeability can be determined from saturation magnetization and anisotropy field as \(\mu_{initial} = 1 + 4\pi M_s/H_k\), where \(H\) is the external field. The complex permeability as a function of frequency at fixed bias field is determined by frequency-swept measurement. The imaginary permeability versus frequency is obtained by using the integration process as described in Ref [7]. We then calculate the real part of permeability from the imaginary part, using Kramers-Kronig relation. Fig. 2 shows the measured spectrum of complex permeability of a 30 nm FeGaB sample at zero bias field and 2000 Oe bias field. The resonance shifts from 2 GHz to 20 GHz with the increase of bias field and the magnitude of permeability is reduced by the applied field. The permeability results on an ultra-thin 2 nm NiFe is presented in Fig. 2(c). The profile of the complex permeability agrees well with the theoretical permeability calculated from Landau-Lifshitz-Gilbert (LLG) equation, which validates the results.

III. PERFORMANCE COMPARISON BETWEEN DIFFERENT METHODS ON PERMEABILITY MEASUREMENTS

A comparison between the reported permeability measurements on magnetic films is summarized in Table I. The new method presented in this study can measure thin-film samples through a much wider frequency bandwidth than any other permeability measurements using microwave transmission line or cavity with vector network analyzer. The measurements on 30 nm FeGaB film show SN ratio of 72 dB, which is the highest sensitivity among all the permeability measurement techniques that we know. In addition, our system is able to detect a 2 nm ultra-thin NiFe film with 28 dB SNR.

IV. CONCLUSION

A new rf magnetic metrology system with the functions of FMR spectrometer and permeameter has been demonstrated with ultra-wide frequency band from 10 MHz up to 26 GHz. The system is capable of characterizing the magnetic properties of the magnetic films with in-plane or perpendicular anisotropy, including complex permeability, FMR linewidth, saturation magnetization, effective anisotropy field, Gilbert damping, inhomogeneous linewidth broadening, and gyromagnetic ratio, through the FMR measurements and analysis.
measurements on permeability have shown much higher SN ratio over the conventional permeameters.
